

A Graphical Representation for Biological Processes in the Stochastic pi-Calculus

Andrew Phillips, Luca Cardelli, Giuseppe Castagna

5.11.2007

- introduction
- stochastic pi-calculus
- graphical calculus
- example: bistable gene network
- conclusion

Introduction

- graphical representation for biological systems
 - static
 - dynamic
 - formalism: graphical calculus
 - equivalent to stochastic π
-
- highlight existence of cycles
 - animate interactions between system components
 - accessibility to non-computer scientists

The Stochastic π -Calculus

a variant with internal transitions and recursive definitions

System

- system $E \vdash P$
- constant environment E
- process P

Biological settings

- process P represents a molecule (gene, protein, etc.)
- an action describes what a molecule can do

Environment

$E ::=$	$X(m) = P$	Definition, $\text{fn}(P) \subseteq m$
	E_1, E_2	Union
	\emptyset	Empty

- definition parametrized by m

The Stochastic π -Calculus

Action

$\pi ::=$	τ_r	Delay
	$!x(n)$	Output
	$?x(m)$	Input

- delay action τ_r
 - represents a change in internal structure
 - the rate r characterises an exponential distribution
 - average duration of the interaction $1/r$
- input and output
 - on a common channel x
 - an interaction of two molecules
 - $\text{rate}(x)$... the interaction rate
- fits the biological reality well

The Stochastic π -Calculus

Process

$P, Q ::= P|Q$ Parallel
 | M Choice
 | $X(n)$ Instance
 | $\nu x P$ Restriction

$M ::= \pi.P + M$ Action
 | 0 Null

- parallel composition $P_1 | \dots | P_M$
 - existence of M molecules in parallel
- choice $\pi_1 P_1 + \dots + \pi_N P_N$
 - ability to react in N different ways
- definition recorded in environment
- restriction used to represent complexes with a private communication $\nu x(P|Q)$

The Stochastic π -Calculus

Execution rules

generally $E \vdash P \xrightarrow{\alpha} E \vdash P'$

Graphical representation

- processes as *nodes*
- *edges* to nested process
- definition in the environment assigns a unique *identifier* to a node
- static visualisation only

The Stochastic π -Calculus

Example of graphical representation

$$Gene(a, b) = \tau_t.(Gene(a, b)|Protein(b)) + ?a.\tau_u.Gene(a, b)$$
$$Protein(b) = !b.Protein(b) + \tau_d$$

- reduction equivalent to stochastic π -calculus
- the same expressive power
- each choice defined separately in the environment
- each node unique identifier
- static and also dynamic visualisation

Graphical Calculus

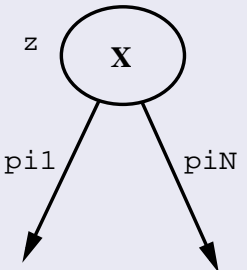

Process

$P, Q ::=$	$P Q$	Parallel
	0	Null
	$X(n)$	Instance
	νxP	Restriction

Environment

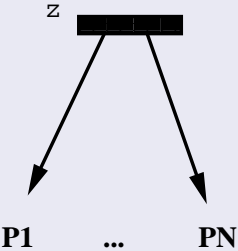

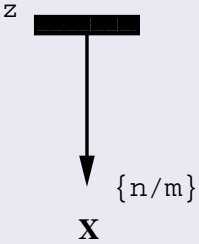

$E ::=$	$X(m) = D$	Definition, $\text{fn}(P) \subseteq m$
	E_1, E_2	Union
	\emptyset	Empty
$D ::=$	P	Process
	M	Choice
	νxD	Restriction
$M ::=$	$\pi.P + M$	Action
	0	Null

Graphical representation - environment

	Choice	Process	Union
E	$X(m) = \nu z (p_{i1}.P1 + \dots + p_{iN}.PN)$	$X(m) = P$	$E1, \dots, EN$
		P	E1 ... EN

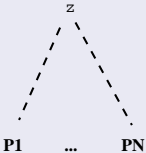

Graphical Calculus

Graphical representation - process

	Null	Parallel	Instance
P	$v z 0$	$v z(P1/.../PM)$	$X(m)=P /- v z X(n)$
P			

Graphical Calculus

Dynamic graphical representation of processes

	Null	Parallel	Instance
P	$v z 0$	$v z(P1/\dots/PM)$	$X(m)=P \text{ /- } v z X(n)$
P			

- substitution token $\{n/m\}$ next to instance
- dotted edge from restricted name z to processes
- node highlighted when at least one token present and any restricted names are connected to the token – the process is "active"

The Stochastic π -Calculus

Gene example of graphical representation

$$Gene(a, b) = \tau_t.(Gene(a, b)|Protein(b)) + ?a.\tau_u.Gene(a, b)$$
$$Protein(b) = !b.Protein(b) + \tau_d$$

Graphical Calculus

Gene example

$$\text{Gene}(a, b) = \tau_t.(\text{Gene}(a, b) | \text{Protein}(b)) + ?a. \text{Blocked}(a, b)$$
$$\text{Blocked}(a, b) = \tau_u. \text{Gene}(a, b)$$
$$\text{Protein}(b) = !b. \text{Protein}(b) + \tau_d$$

Example of behaviour

$$1 \xrightarrow{t} 2 \xrightarrow{?a} 3 \xrightarrow{u} 2$$

Bistable Gene Network

$z = \text{inhibit, bind}$

$$a(z) = \tau_{tA} \cdot (A(z) | a(z))$$

$$A(z) = \nu u (\tau_{dA} + !\text{bind}(u) \cdot A_B(u) + !\text{inhibit}(u) \cdot A_b(u, \text{inhibit}, \text{bind}))$$

$$A_b(u, \text{inhibit}, \text{bind}) = ?u \cdot A(z)$$

$$A_B(u) = \tau_{dAB}$$

$$b(z) = \tau_{tB} \cdot (B(z) | b(z)) + ?\text{inhibit}(u) \cdot b_A(u)$$

$$b_A(u) = \tau_{tB'} \cdot (B(z) | b_A(u)) + !u \cdot b(z)$$

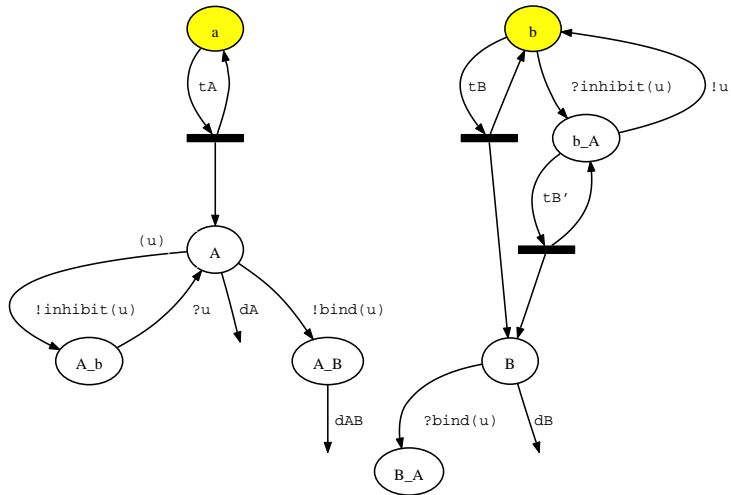

$$B(z) = \tau_{dB} + ?\text{bind}(u) \cdot B_A(u)$$

$$B_A(u) = 0$$

Bistable Gene Network

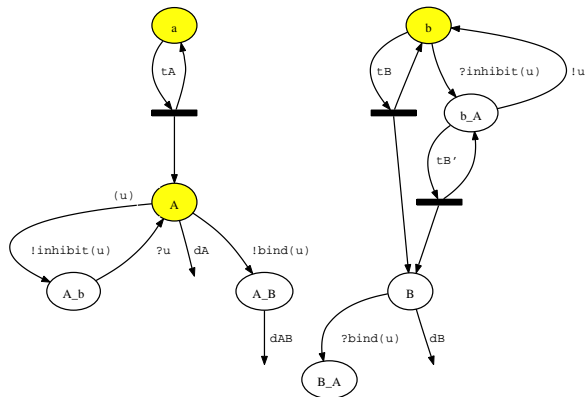

Bistable Gene Network - First Possible Behaviour

Bistable Gene Network - First Possible Behaviour

t_a (A is transcribed first)

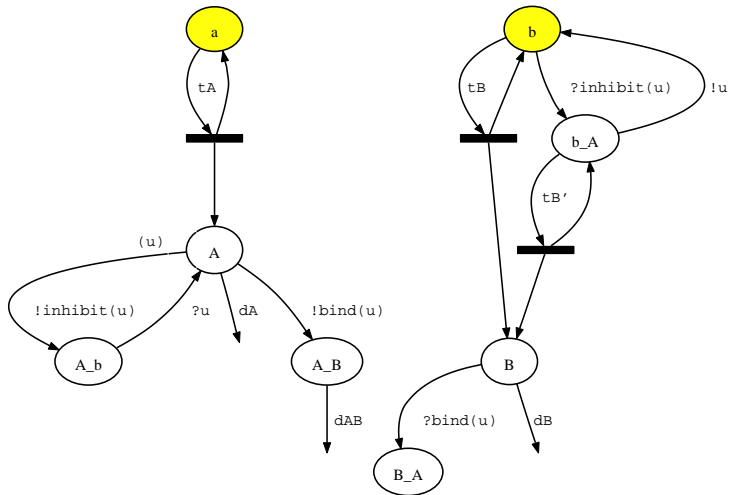

Bistable Gene Network - First Possible Behaviour

inhibit (*A* binds to gene *b* and inhibits production of protein *B*)

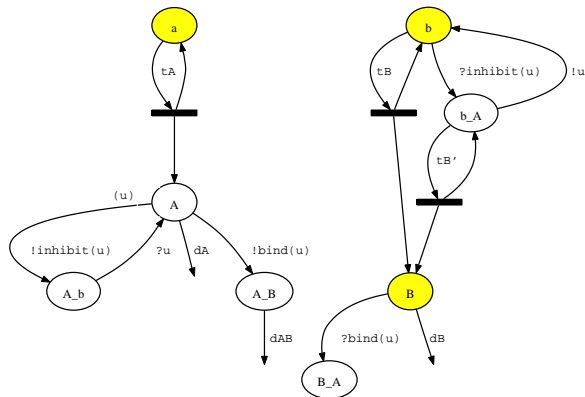

Bistable Gene Network - Second Possible Behaviour

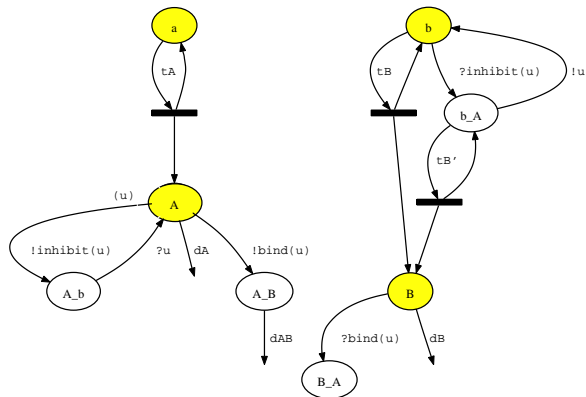

Bistable Gene Network - Second Possible Behaviour

t_b (B is transcribed first)

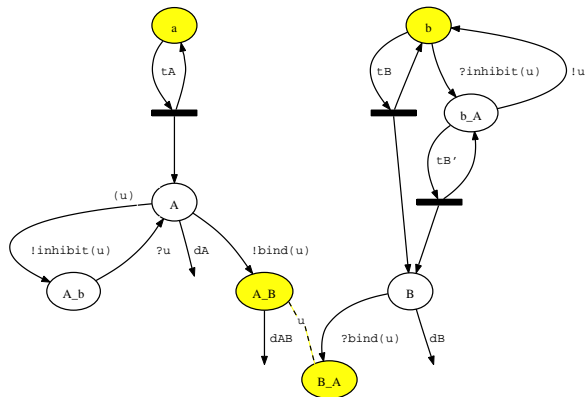

Bistable Gene Network - Second Possible Behaviour

t_a (A is transcribed then)

Bistable Gene Network - Second Possible Behaviour

bind (protein A binds to protein B)

Conclusion

- graphical calculus
- expressive power of stochastic pi-calculus
- static and dynamic visualisation
- examples
 - bistable gene network
 - mapk cascade
- SPiM
 - tool
 - programming language
 - graph generation
 - simulation
